① $32 \times 32 \times 32 = 32768 = A$

$32 \times 32 \times 32 = \boxed{32768 = B \text{ accessed}}$

$32768 + 32768 = \boxed{65536 \text{ total accessed}}$

$65536 \times 4 = \boxed{262144 \text{ bytes}}$

② $(8 \times 8) \times (8 \times 8) = 4096$ A floats = B floats

$4096 + 4096 = 8192 \times 4 = 32768$ bytes $= \boxed{32KB \text{ DRAM traffic}}$

③ $262144 / 32768 = 8$

This ratio is related to $N/T = 32/8 = 4$, which is the 4x4 grid tiles. $T = 4$ $N = 32$ $32/4 = 8$

④ FLOPs $= 2 \times 32 \times 32 \times 32 = 65{,}536$ FLOPs Naive and Tiled

$65{,}536 / 10T = 6.55 \times 10^{-9} = 6.55$ ns Compute time Naive and Tiled

$262KB / 320\ GB/s = 819.2$ ns Naive

$32KB / 320\ GB/s = 102.4$ ns Tiled

I believe the bottle neck is memory bound since even with the tiled at 102 ns, compared to the compute 6.55 ns, it is a big difference.
